UDHR presenter cheat sheet

Keep beside the laptop. Left column: what to say. Right column: what to click. Tags show the rubric row each part earns marks for (45 marks are given for the live demo).

Before you start (10 min early)

- Open **udhr-system.onrender.com** a few minutes early: the free server takes about 1 min to wake up.
- Window 1: **SYSADMIN001** → Security alerts (the Demo inbox shows the "texts" and "emails").
- Window 2: the role you're showing. Have the authenticator phone for each account ready.
- Tick "This is my own device" so codes aren't asked again on this laptop.
- Check **System status** says **Connected**.

Logins

- Front desk `ADMIN001` · Nurse `NUR001` · Doctor `DOC001` · Pharmacist `PHARM001`
- System admin `SYSADMIN001` (your own password)
- Patient: ID `9001015000083`, born 1 Jan 1990, your PIN. Forgot it? Use "Forgot your PIN?" and read the code in the Demo inbox.
- Locked out? System admin → Accounts → Manage ▾ → Reset password / Reset sign-in app.

Outline section	What to say	What to show
Introduction	Paper files don't follow patients between clinics, so history, allergies and medication get lost. UDHR gives every patient one digital record that any clinic in the network can use, under POPIA rules.	The sign-in page: Patient or Healthcare staff.
Description of the system	Six roles, each with its own screen: front desk, nurse, doctor, pharmacist, patient and system admin. Each sees only what their job needs; the system admin never sees clinical records.	Sign in as two roles and point out the different menus.
User requirements	Check in, record vitals, diagnose and prescribe, dispense, and patients viewing their own record. Plus forgot PIN/password without queuing, and an alert if an account is misused.	"Forgot your PIN?" → Text me a code → read it in the Demo inbox → new PIN.
System requirements	Web app (React + Spring Boot, Java 17) on Render, PostgreSQL database. Security: encrypted passwords, sign-in tokens that expire, two-step sign-in, a code for each new device, lockout after 5 wrong tries.	Sign-in security panel: two-step on, remembered devices, "Forget all devices".
Use cases Functionality	Main use case: one patient through the clinic. Extra ones: opening a record outside today's list needs a reason; the admin responds to a security alert.	Front desk check-in → Nurse vitals (abnormal values flagged) → Doctor diagnose + prescribe (allergy warning) → Pharmacist Dispense (stock drops by itself) → Patient portal.
Data and database Data & error handling	**Path:** `spring.datasource.url=${SPRING_DATASOURCE_URL}` in `application.properties`, set on Render, not in the code. **Empty:** DataSeeder fills a new database with starter data. **Moved or down:** one red banner on every screen, nothing half-saved, no error codes.	System admin → **System status**: Connected, address (password hidden), where it's set, record counts. Open code: `health/DatabaseGuardFilter.java`, `config/DataSeeder.java`.
DFD / ERD	Main tables: patients, staff, facilities, visits, vitals, diagnoses, prescriptions, stock, audit_logs. **Added after submission:** trusted_devices (remembered devices), demo_emails (demo inbox), reset-code columns. Every action writes to audit_logs, which feeds the alerts and reports.	If asked about new tables: "we added them for security after submitting; here they are working."
Typing limits and error prevention Database connection	Every text box has a limit matching its database column (names 100, notes 2,000). Wrong data is refused before saving.	Pharmacist → Stock → Update stock: enter 500001 (refused), Remove with no reason (refused). Nurse: blood pressure "abc" (refused).
Testing	134 automated tests run on every change (GitHub Actions), plus browser testing as every role. Example test cases: 5 wrong codes cancel the code; 500001 stock refused; database down gives the friendly message; doctor can't open a stranger's record without a reason.	Show the green ticks on GitHub, or one test file, e.g. `DatabaseDownTest.java`.
Reports Reports	Reports support the business: what was prescribed and dispensed, stock running low or expiring, and who did what, when.	System admin → Reports (CSV download) → Audit trail (filter by staff) → Security alerts.
User interface User interfaces	One font, sentence-case labels, standard blue links, the same buttons everywhere, grey read-only fields, plain background, left-aligned headings.	Press the browser **Back** button: it returns to the previous screen and typed text is still there.

If something goes wrong

- **Slow first load:** the free server is waking up; wait about 1 min.
- **"Too many attempts":** wait 15 min, or reset it as the system admin.
- **Red database banner:** it's the error handling working. Say so, then check System status.
- **No code arrived:** codes are in Security alerts → Demo inbox (system admin window).

Likely questions

- **Someone steals my ID book?** They still need the PIN, and a new device needs a code texted to your phone.
- **A doctor's account is hacked?** A reason is needed to open records outside today's list, alerts go to the admin, and "End all sessions" stops it.
- **POPIA?** Every access is logged, the admin can't see clinical data, and emails leave patient details out.
